

Characterization and spatio-temporal dynamics of *Cylindrospermopsis raciborskii* in an Amazonian Lagoon, Ecuador

(Caracterización y dinámica espacio-temporal de *Cylindrospermopsis raciborskii* en una laguna amazónica, Ecuador)

Judith Venegas¹, Pablo Castillejo Pons², Susana Chamorro Arias², Ivonne Carrillo Paredes², Eduardo Lobo Alcayaga³

Abstract:

The cyanobacteria *Cylindrospermopsis raciborskii*, is a fresh water ubiquitous species from tropical to temperate weather. It is potentially capable of producing toxins. Thus it is necessary to monitor its presence in fresh waters associated to recreational use activities and human consumption. There are official reports and one thesis reporting the presence of *C. raciborskii* in Ecuador. Nevertheless, this country does not appear in the latest distribution maps of this species in the scientific literature. In this article, we report the presence of *C. raciborskii* in Ecuador, together with the characterization of the environmental conditions of one of the habitats where this species is present: the Limoncocha lagoon, province of Sucumbíos.

Keywords: Amazon; cyanobacteria; South America; Limoncocha.

Resumen:

La cianobacteria *Cylindrospermopsis raciborskii* es una especie omnipresente en agua dulce desde el clima tropical hasta el clima templado. Es potencialmente capaz de producir toxinas. Por lo tanto, es necesario monitorear su presencia en aguas dulces asociadas a actividades de uso recreativo y consumo humano. Hay informes oficiales y una tesis que informan la presencia de *C. raciborskii* en Ecuador. Sin embargo, este país no aparece en los últimos mapas de distribución de esta especie en la literatura científica. En este artículo, reportamos la presencia de *C. raciborskii* en Ecuador, junto con la caracterización de las condiciones ambientales de uno de los hábitats donde esta especie está presente: la laguna Limoncocha, provincia de Sucumbíos.

Palabras clave: Amazonas, cianobacteria, Sudamérica, Limoncocha.

1. Introduction

Cyanobacteria are photosynthetic prokaryotic organisms present in fresh water ecosystems. Some of the species are highly tolerant to extreme conditions as thermal springs over 60 °C, hypersaline lakes, or polar regions (Bonilla et al., 2012). Cyanobacteria can grow sharply under certain environmental conditions, phenomenon called bloom (Smayda, 1997). Some of them are able to produce toxins that confer a competitive advantage against other groups. This is the case of *Cylindrospermopsis raciborskii* (Woloszynska, 1912), a filamentous cyanobacteria (order Nostocales) able to fix nitrogen and to form akinetes, a thick-walled dormant cell that serves as a survival structure. Thus

³ Universidade de Santa Cruz do Sul, Santa Cruz do Sul, Brasil (lobo@unisc.br).

its presence in Ecuador might be a potential environmental and public health hazard (Stüken et al., 2006).

Usually, the Asiatic and Australian *C. raciborskii* strains are capable of producing the toxin cylindrospermopsina, while the South American synthesizes PSP (Paralytic Shellfish Poison). Nevertheless, European, African and North American strains have not shown any toxin production so far (Stüken et al., 2006).

The first report about *C. raciborskii* toxicity was in 1985, from a strain isolated in a water reservoir for human consumption in Australia (Hawkins et al., 1985). In 1996, in Caruaru, Brazil, 52 people died due to a *C. raciborskii* bloom in another water reservoir for human consumption (Azevedo et al., 2002).

C. raciborskii has been described for the first time in Java Island, Indonesia in 1912. Since then, it has been reported in plenty of tropical locations until 1937, when Skuja (1937) reported it in Europe for the first time. Nowadays, *C. raciborskii* is found in both hemispheres, in rivers, lakes, reservoirs being a cosmopolite species (Antunes et al., 2015). The increasing presence in temperate climates began to draw the attention of the scientific community (Padisák, 1997; Antunes et al., 2015).

In Ecuador, *C. raciborskii* has been reported in Daule-Peripa reservoir and Daule river (Provincia de Guayas) in 2011 (Prado M. & Bucheli R., 2012) and Yaguacocha lagoon (Provincia de Imbabura) by Saelens (2015). Nevertheless, these findings have not been reported in the scientific literature, thus Ecuador has been excluded from the latest report on *C. raciborskii* geographical distribution proposed by Antunes in 2015.

We report the first record of *C. raciborskii* in the Ecuadorian Amazon region, and describe its hosting habitat: the Limoncocha Lagoon. In addition, this work aims to update the worldwide presence of *C. raciborskii*, adding Ecuador to the distribution area compiled by Antunes (2015).

2. Material and Methods

2.1 Study area and field sampling

Limoncocha lagoon belongs to the Amazonas river basin. It is located in Shushufindi County (called Canton), in the Limoncocha Biological Reserve (long -76,600000; lat 0,400000; 244 m) (Figure 1). This wetland, designed as a RAMSAR site since 1998 (Mae, 2016), contains both lentic and lotic ecosystems, whose central axis is the Limoncocha lagoon.

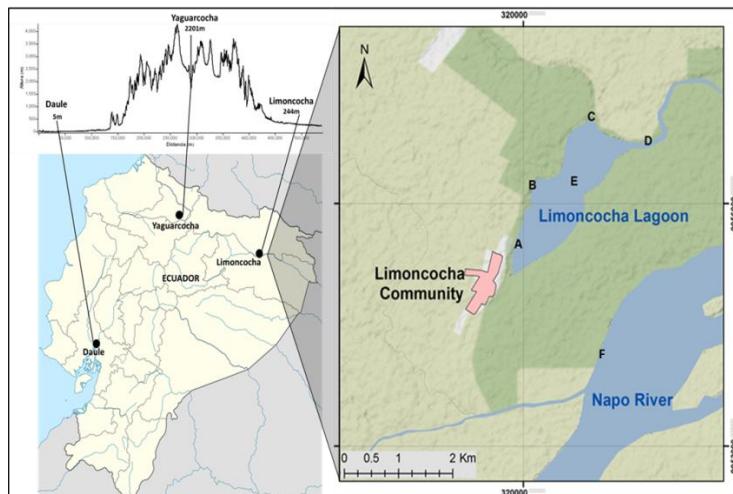

Figure 1. Places in Ecuador where *C. raciborskii* has been found and water sampling spots at Limoncocha lagoon: A: Embarcadero; B: Playayacu; C: Pishira river; D: Caño; E: Deep Zone. F: Napo River. Instituto Geográfico Militar, 2017.

2.2. Water Sampling

The locations for sampling were randomly picked. Two sampling points were selected at the confluence of two creeks called Pishira River and Playayacu River, which present sewage water running off from the village Parroquia de Limoncocha (follow Limoncocha village). The other three sites were selected randomly: Caño, Embarcadero (close to the lagoon shore) and Deep Zone (in the center of the lagoon) (*Figure 1*). Samples were collected in 250 mL plastic bottles (Vand Dorn Eijkenkamp ©) and stored at 4°C for later analysis.

2.3. Physicochemical parameters

Temperature, pH, dissolved oxygen and conductivity were measured in situ with Multiparameter HACH ©. Phosphate and nitrate anions, ammonia, ODB5, were determined with HACH method (Hach, 2000) using ascorbic acid 8048, HACH 4000 spectrophotometer with a 890nm wave length. The ammonia was determined HACH 8038 colorimetric method, HACH 400 spectrophotometer with a length wave of 425nm.

2.4. Cyanobacteria species identification

The collected specimens were identified based on taxonomic analyses (Komárek & Komártková-Legnerová, 2003) under the optic microscope (Olympus cx31), 100x. Photographs were taken using "Applied vision 4" camera system (Ken-a-vision, n.d.).

2.5. Data analysis

Correlation between temperature and density of *C. raciborskii* was established by using the Pearson coefficient of correlation "r" with $\alpha = 0.05$. Prior to the analysis, the biological data was base-e Log transformed. The analyses were performed using PAST software (Hammer et al., 2001).

3. Results and discussion

3.1 Temperature, pH, salinity, ammonia nitrogen and phosphorus dynamics in Limoncocha lagoon

Limoncocha lagoon is highly eutrophicated due to natural processes and sewage from nearby Limoncocha village (Durañona, 2005). Its location (Fig.1) determines a tropical rainy climate with a daily average temperature of 28°C. The lagoon temperature ranges from 17°C close to Pishira River affluent mouth to 32,3°C from the warmest areas of the surface water in the middle of the lagoon. The pH range ranges from 6 to 9, very suitable values for *C. raciborskii* growth (Briand et al., 2002; Padisák, 1997; Padisák & Reynolds, 1998).

The salinity is low as conductivity ranges up to 180 µS/cm, are congruent with those for freshwater values (salt content below 2000ppm) (Llamas & Custodio, 1976).

Ammonia levels contributed to the total inorganic nitrogen detected since nitrates and nitrites were out of our detection threshold. The concentration of ammonia varied from 0,46 to 0,56 mg/L consistent with the values for a eutrophic lake (*Table 1*).

Dissolved phosphorus ranged from 0,2 mg/L at the deep zone to 1,6 µg/L at mouth of Playayacu River, congruent with the values for a eutrophic lake.

Table 1. Physic-chemical parameters at sample stations in September (S) and November (N): Temperature (T), pH, conductivity (C), nitrates (NO_3^-), ammonia (NH_4^+), orthophosphate (PO_4^{3-}), and biological oxygen demand (ODB_5).

Samples	Station	Month	T (°C)	pH	C ($\mu\text{s}/\text{cm}$)	[NO_3^-] (mg/L)	[NH_4^+] (mg/L)	[PO_4^{3-}] (mg/L)	ODB_5 (mg/L)
BS	Playayaku	Sep	29,4	8,96	39,6	0,3	0,46	1,6	0,66
CS	Pishira	Sep	28,4	8,20	3,52	0,4	0,47	0,5	0,69

FN	Napo	Nov	31	8,4	175,9	0,3	0,57	1,6	0,33

3.2. *C. raciborskii* at Limoncocha lagoon:

The thricomes collected were 30 μm up to 70 μm long, no circular morpho types were found. Only a 23 per cent of the samples observed contained two heterocysts per thricome being the majority the single heterocyst thricome (Figure 2.a). These structures are specialized nitrogen-fixing cells formed during nitrogen starvation (Berman-Frank et al., 2003).

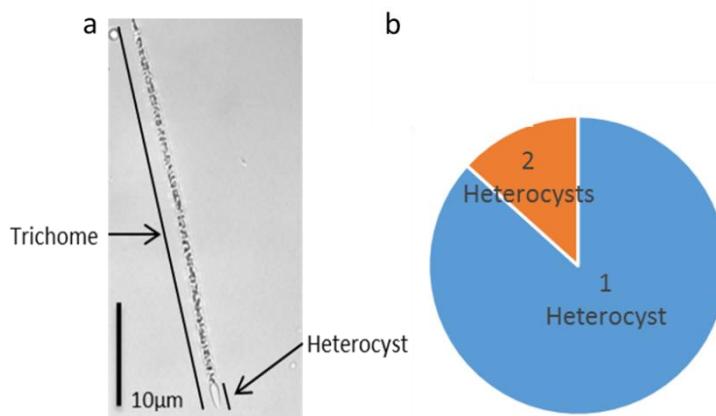

Figure 2. *C. raciborskii* thricome from Limoncocha lagoon under optical microscope (100x). b: percentage of thricomes with one and two heterocysts.

3.3. *C. raciborskii* potential blooms in Limoncocha lagoon.

Temperature, pH and salinity data observed in the lagoon are suitable for *C. raciborskii* growth throughout the year. Furthermore, there is a strong correlation (Figure 3) between increase of temperature and density of *C. raciborskii* thricomes at the lagoon ($r = 0,85$; $p < 0,05$) (Figure 3). Eutrophication decrease the light intensity into the water, thus Secchi deep reaches just 30cm from the water surface (Figure 4). This confers an adaptive advantage to the shade-tolerant phytoplankton (Schwaderer et al., 2011) as *C. raciborskii* (Briand et al., 2002).

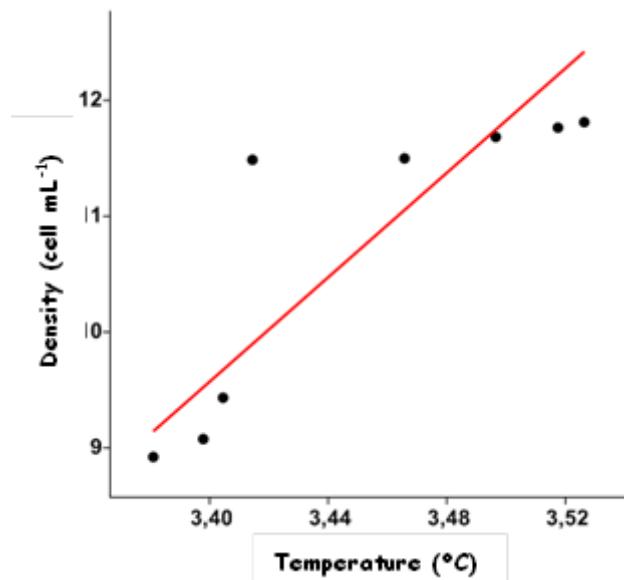

Figure 3. Temperature (°C) versus density of *C. raciborskii* (cell mL⁻¹). Data were LN (X+1) transformed. Coefficient of Correlation, $r = 0,85$ ($p < 0,05$).

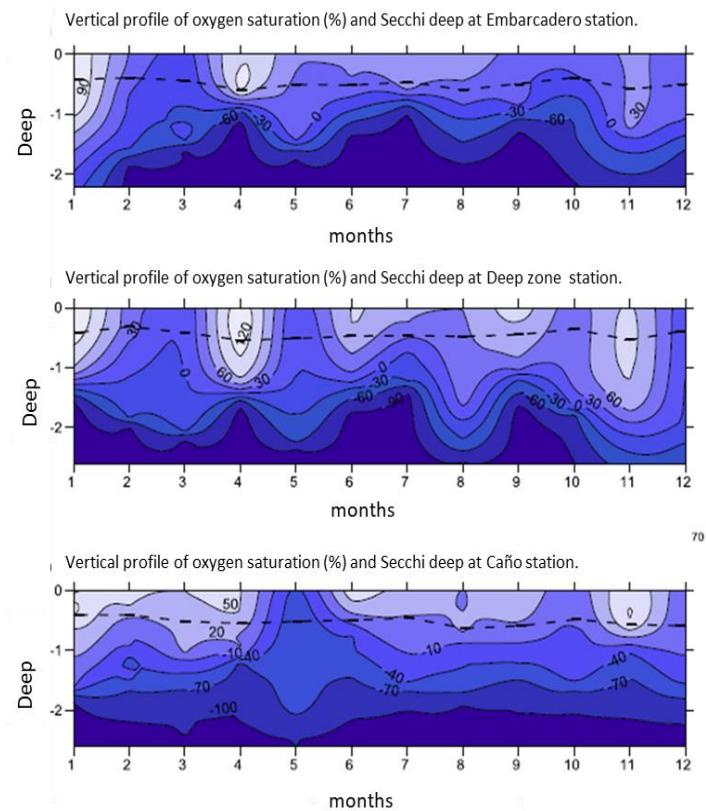

Figure 4. Secchi Deep and oxygen saturation in Limoncocha lagoon (Martín Hernández, 2015). The dashed line indicates the Secchi depth.

C. raciborskii is associated with low salinity conditions (Padisák, 1997) as such found in the Limoncocha lagoon, although it could also live with moderate salinity (Calandrino & Paerl, 2011).

Regarding the nitrogen assimilation, some studies have shown *C. raciborskii* to have preference for ammonia (Spröber et al., 2003) which is present in the lagoon (Table 1). The absence of thricomes with two heterocysts (Figure 2.b) matches with the fact that the

amount of heterocysts is inversely proportional to the inorganic nitrogen concentration in the media (Bouvyli et al., 1999; Briand et al., 2002).

C. raciborskii has a great autonomy regarding phosphorus needs for it is capable of assimilating and storing phosphorus easily (Wu et al., 2009; Isvanovics et al., 2000). Thus, low phosphorus concentration in the lagoon does benefit *C. raciborskii* over other organisms. Furthermore, Bar-Yosef et al. (2010) showed that lack of inorganic phosphorus leads the discharge of CYN hepatotoxin by Aphanizomenon strain causing the death of microorganisms and so, releasing inorganic phosphates.

The N:P ratio is low in the lagoon (*Table 1*), which favors *C. raciborskii* proliferation in eutrophic environments (Chislock et al., 2014).

In general, Limoncocha lagoon conditions are auspicious to *C. raciborskii* blooms, representing a potential risk for the communities living on the lagoon shore. The *Table 2* shows the concentration of *C. raciborskii* in September and November. Concentrations above 100.000 cells/mL are consider a risk for the population according to the World Health Organization (1998), as those found in Playayacu River mouth.

Table 2. *C. raciborskii* density (cel/mL) per month.

Month	Playayaku (B)	Pishira (C)	Caño (D)	Napo (F)
September	128750	12500	8750	7500
November	135000	118750	98750	97500

3.4. Ocurrence of *C. raciborskii* in Ecuador

Cylindrospermopsis raciborskii has been reported at river Daule basin, (-80,00766382550 -1,96826402406, 5 m altitude above sea level) (Prado M. & Bucheli R., 2012); Yaguarcocha lagoon (-76,60000000000 -0,40000000000; 2.201 m above sea level) (Saelens, 2015) and Limoncocha Lagoon (-76,60000000000-0,40000000000; 244 m above sea level) (*Figure 1*).

Ecuador is located on either side of the equator and crossed by the Andes range with a maximum altitude of 6,268 m: the snowcap Chimborazo volcano. Thus, the highest biotopes in the world are found in this country, since the snow level stays at ca 5000m. Saelens reported which is so far the highest location record for *C. raciborskii*: the Yaguarcocha lagoon, 2,201m (Saelens, 2015) (*Figure 1*). We expect to find the cyanobacteria even at higher altitudes, where the temperature range matches that from the lake Constance, in Otawa, Canada, one of the coldest places where *C. raciborskii* has been reported (Hamilton et al., 2005).
